Sampling and Meshing Curved 3D Domains by Delaunay Refinement

Jean-Daniel Boissonnat INRIA Sophia-Antipolis

Winter School on Algorithmic Geometry ENS-Lyon January 2010

Winter School on Algorithmic Geometry Sampling and Meshing Curved Domains

Applications

- visualization and graphics applications
- CAD and reverse engineering
- geometric modelling in medecine, geology, biology etc.
- autonomous exploration and mapping (SLAM)
- scientific computing : meshes for FEM

Two main issues

Sampling

- How do we choose points in the domain ?
- What information do we need to know/measure about the domain ?

Topology and Geometry

- 1. How do we connect the points ?
- 2. Under what sampling conditions can we compute a good approximation of the domain ?
- 3. What is a good approximation ?

State of the art : implicit surface meshing

Marching cube

Lorensen & Cline [87] Lopez & Brodlie [03] : topological consistency Plantiga & Vegter [04] : certified topology using interval arithmetic

Morse theory

Loose ε -samples are $\varepsilon(1 + O(\varepsilon^2))$ -samples

Sketch of proofs

Winter School on Algorithmic Geometry Sampling and Meshing Curved Domains

(4) (3) (4) (3)

크

Surfaces : local properties 1/2

Chord lemma

 $\forall p, q \in S, \|p - q\| \leq 2\varepsilon \text{lfs}(p) \Rightarrow \sin(pq, T_p) \leq \varepsilon$

크

Surfaces : local properties 2/2

Facet normal lemma

Let f = pqr be a facet of $\text{Del}(\mathcal{P})$ and assume that $\hat{p} \ge \frac{\pi}{3}$. If the circumradius ρ_f of f is at most $\varepsilon \operatorname{lfs}(p)$, then $\sin(n_f, n_p) \le 2\varepsilon$.

Proof

$$\sin(n_f, n_p) = \sin(pc_B c_D) = \frac{\|p - c_D\|}{\|p - c_B\|} = \frac{\rho_D}{\mathrm{lfs}(p)}$$

$$\hat{p} = \alpha_q + \alpha_r \ge \frac{\pi}{3} \stackrel{\text{wlog}}{\Rightarrow} \alpha_q \ge \frac{\pi}{6}$$

$$q
ot\in D \cup D' \; \Rightarrow \; \|p - q\| \ge 2
ho_D \sin lpha_q \ge
ho_D$$

$$\frac{\rho_D}{\mathrm{lfs}(p)} \leq \frac{\|p-q\|}{\mathrm{lfs}(p)} \leq \frac{2\rho_f}{\mathrm{lfs}(p)} \leq 2\varepsilon$$

Proof of homeomorphism (sketch)

The conditions of the Nerve Th. are satisfied

1. Any edge of $Vor_{|S}(\mathcal{P})$ intersects S in one point

$$\begin{aligned} \|x - p\| &\leq \varepsilon \operatorname{lfs}(x) \qquad (*) \\ \|y - p\| &\leq \varepsilon \operatorname{lfs}(y) \leq \frac{\varepsilon}{1 - \varepsilon} \operatorname{lfs}(x) \\ \Rightarrow \|x - y\| &\leq 2\frac{\varepsilon}{1 - \varepsilon} \operatorname{lfs}(x) \\ \Rightarrow [xy] \stackrel{|}{\sim} n_x \approx n_\rho \end{aligned}$$

 $[xy] \perp e^*$ and the facet lemma $\Rightarrow [xy] \wr n_p$

2. Similar arguments show that faces of higher dimensions are also topological balls

 $\pi: \mathrm{Del}_{|\mathcal{S}}(\mathcal{P}) \to \mathcal{S}$ is injective

$x \in S$ n_x the normal to S at x l_x the normal fiber $[x - r n_x, x + r n_x]$ where $r = \varepsilon \operatorname{lfs}(x)$

Injectivity lemma

If \mathcal{P} is a loose ε -sample for $\varepsilon \leq 0.12$, then I_x intersects $\mathrm{Del}_{|S}$ in at most one point

< 同 > < 回 > < 回 > <

크

Proof of the injectivity lemma (by contradiction)

f, *f'* two consecutive facets of $\text{Del}_{|S}(\mathcal{P})$ that intersect l_x

 $T = t_1, ..., t_s$ the set of tet. intersected by l_x between *f* and *f'*

 $\begin{aligned} \gamma &= (\textit{c}_{\textit{f}} = \textit{c}_{0}, \textit{c}_{1}, ..., \textit{c}_{\textit{s}}, \textit{c}_{\textit{f}'} = \textit{c}_{\textit{s+1}}) \\ \textit{c}_{\textit{i}} &= \texttt{cc of } \textit{t}_{\textit{i}}, \gamma \subset \texttt{skel}(\texttt{Vor}(\mathcal{P})) \end{aligned}$

with
$$s_i = (c_{i+1}-c_i)/\|c_{i+1}-c_i\|$$

• c_f and $c_{f'}$ are consecutive points of $l_x \cap S$

$$\Rightarrow (n_{c_f} \cdot s_f) \times (n_{c_{f'}} \cdot s_{f'}) < 0$$

- ► Facet normal lemma $\Rightarrow (n_{c_f} \cdot s_f) \times (n_{c_{f'}} \cdot s_{f'}) < -1 + O(\varepsilon^2)$
- ► Delaunay \Rightarrow $(n_x \cdot s_i) \times (n_x \cdot s_{i+1}) > 0$ $\Rightarrow (n_x \cdot s_f) \times (n_x \cdot s_{f'}) > 0$

・ロト ・ 一日 ト ・ 日 ト

- Normal variation lemma $\Rightarrow n_{c_f} \approx n_x \approx n_{c_{t'}}$
- Contradiction !

$\pi: \mathrm{Del}_{|\mathcal{S}}(\mathcal{P}) \to \mathcal{S}$ is surjective

If \mathcal{P} is a loose ε -sample of \mathcal{S} with $\varepsilon \leq$ 1.12, then \mathcal{S} is covered at least once by π

Proof

- any edge of Del_{|S} belongs to exactly two facets of Del_{|S}
- every cc of S contains \geq 1 vertex of $\text{Del}_{|S}(\mathcal{P})$
- by contradiction : there exists an edge where the injectivity lemma is violated

Isotopy

If \mathcal{P} is an ε -sample for $\varepsilon \leq 0.12$, π induces an isotopy that maps $\mathrm{Del}_{|S}(\mathcal{P})$ to S

The isotopy moves the points by $O(\varepsilon^2)$

(日本) (日本) (日本)

르
Isotopy

If \mathcal{P} is an ε -sample for $\varepsilon \leq 0.12$, π induces an isotopy that maps $\mathrm{Del}_{|\mathcal{S}}(\mathcal{P})$ to \mathcal{S}

The isotopy moves the points by $O(\varepsilon^2)$

Proof

- Homeomorphism: π is bijective and bicontinuous
- ▶ Isotopy : f : Del_{|S}(\mathcal{P}) × [0, 1] → \mathcal{S} , $f(x, t) = x + t \frac{\pi(x) x}{\|\pi(x) x\|}$
- ► Fréchet distance : trivially ≤ ε sup_{x∈S} lfs(x) for a better bound, adapt the chord lem.

A B b A B b

Surface mesh generation by Delaunay refinement

- $\begin{aligned} \phi : \mathcal{S} &\to \mathbb{R} \text{ = Lipschitz function} \\ \forall x \in \mathcal{S}, \ 0 < \phi_{\min} \leq \phi(x) < \varepsilon \mathrm{lfs}(x) \end{aligned}$
- ORACLE : For a facet f of $\text{Del}_{|S}(\mathcal{P})$, return c_f , r_f and $\phi(c_f)$
- A facet *f* is bad if $r_f > \phi(c_f)$

[Chew 1993, B. & Oudot 2003]

Surface mesh generation by Delaunay refinement

 $\begin{aligned} \phi : \mathcal{S} &\to \mathbb{R} \text{ = Lipschitz function} \\ \forall x \in \mathcal{S}, \ 0 < \phi_{\min} \leq \phi(x) < \varepsilon \mathrm{lfs}(x) \end{aligned}$

ORACLE : For a facet f of $\text{Del}_{|S}(\mathcal{P})$, return c_f , r_f and $\phi(c_f)$

A facet *f* is bad if $r_f > \phi(c_f)$

Algorithm

INIT compute an initial (small) sample $\mathcal{P}_0 \subset S$ REPEAT IF *f* is a bad facet *insert_in_Del3D(c_f) update* \mathcal{P} and $\text{Del}_{|S}(\mathcal{P})$

UNTIL all facets are good

[Chew 1993, B. & Oudot 2003]

過す イヨト イヨト

The algorithm terminates

Properties of the output

- The output sample \mathcal{P} is
 - ► a covering : (loose ε -sample) $\forall x \in S, d(x, \mathcal{P}) \le \phi(x)(1 + O(\phi^2(x))) \le \varepsilon (1 + O(\varepsilon^2) \operatorname{lfs}(x))$

► a packing :
$$\forall p \in \mathcal{P}, d(p, \mathcal{P} \setminus \{p\}) \ge \min(\phi(p), \phi(q))$$

 $\ge \phi(p) - \|p - q\|$
 $\ge \frac{1}{2}\phi(p)$

$$\blacktriangleright |\mathcal{P}| = O\left(\int_{\mathcal{S}} \frac{dx}{\phi^2(x)}\right)$$

- $\operatorname{Del}_{|\mathcal{S}}(\mathcal{P})$ is a good approximation of \mathcal{S}
- ► all facets have a bounded aspect ratio $\frac{r_f}{l_f} \leq \frac{\phi(c_f)}{\min_{x \in vert(f)} \phi(x)}$

- 同下 - ヨト - ヨト

Size of the sample = $O\left(\int_{\mathcal{S}} \frac{dx}{\phi^2(x)}\right)$

Proof

Let $\rho(x) = \inf\{r : |B(x,r) \cap \mathcal{P}| = 2\}$ and $B_{\rho} = B(\rho, \frac{\rho(\rho)}{2}), \rho \in \mathcal{P}$

$$\begin{split} \int_{S} \frac{dx}{\rho^{2}(x)} &\geq \sum_{\rho} \int_{(B_{\rho} \cap S)} \frac{dx}{\rho^{2}(x)} & \text{(the } B_{\rho} \text{ are disjoint)} \\ &\geq \frac{4}{9} \sum_{\rho} \frac{\operatorname{area}(B_{\rho} \cap S)}{\rho^{2}(\rho)} & \rho(x) \leq \rho(p) + \|p - x\| \\ &\geq \frac{4}{9} \sum_{\rho} \frac{3}{16} \pi = \frac{\pi}{12} |\mathcal{P}| &\leq \frac{3}{2} \rho(\rho)) \end{split}$$

▲御 ▶ ▲ 臣 ▶ ▲ 臣 ▶ 二 臣

$$\begin{aligned} \forall x \in B_{p}, \qquad & \rho(x) \geq \rho(p) - \|x - p\| \geq \frac{1}{2} \ \rho(p) \\ & \rho(p) = \|p - q\| \geq \phi(p) - \|p - q\| \Rightarrow \rho(p) \geq \frac{\phi(p)}{2} \\ & \phi(x) \leq \phi(p) + \frac{\rho(p)}{2} \leq \frac{5}{2} \ \rho(p) \leq 5\rho(x) \end{aligned}$$

Less demanding oracle

 $\operatorname{Vor}_{|S}^{\pm}(\mathcal{P}) = \text{edges of } \operatorname{Vor}(\mathcal{P}) \text{ that intersect } S$ an odd number of times

if $S = f^{-1}(x)$, deciding whether an edge e = [pq] belongs to $\operatorname{Vor}_{|S|}^{\pm}(\mathcal{P})$ reduces to evaluating the sign of f at p and q

The isotopy proof still holds

3

Computing lfs(x) is difficult

Computing $rch(S) = inf_{x \in S} lfs(x)$ is much easier rch(S) is either

- a local minimum of the smallest radius of curvature or
- the radius of a sphere with a diameter binormal to S

Computing lfs(x) is difficult

Computing $rch(S) = inf_{x \in S} lfs(x)$ is much easier rch(S) is either

- a local minimum of the smallest radius of curvature or
- the radius of a sphere with a diameter binormal to S

$$F(p) = 0$$

$$F(q) = 0$$

$$(p-q) \times \nabla f(p) = 0$$

$$(p-q) \times \nabla f(q) = 0$$

$$\lambda (p-q)^2 = 1$$

Multi-view 3D reconstruction

[Aganj et al 2007]

(日)

Multi-view 3D reconstruction: Recovering the 3D shape of an object from

several images taken from different viewpoints

Shape-from-silhouettes: Only uses foreground/background segmentations

Problem statement

Usual hull: Intersection of the visual cones of the different cameras

- Very fast
- 8 Coarse reconstruction: OK for rendering

Previous work

- Volumetric methods
 - Fast, straightforward
 - 8 High memory cost
 - 8 Huge output mesh
 - 8 Discretization artefacts (stair-casing effect)
- L Exact polyhedral intersection (Franco & Boyer, 2003)
 - Very fast
 - 8 Low quality mesh
 - ⊗ Noisy/inconsistent silhouettes ➡ numerical instabilities

Delaunay meshing approach

Multi-view oracle:

A Delaunay tetrahedron is part of the approx. visual hull ⇔
Its circumcenter projects inside the silhouette in all views

Refinement criterion = reprojection error

A boundary facet is good

⇔

All projections are closer from the silhouette boundary than a user-defined threshold in all views

Pros and cons

- 8 Slower
- C High quality mesh
- © Reprojection error control (one-sided)

Polyhedral intersection Marching cubes Delaunay

Delaunay meshing

NB: same mesh size

Spatio-temporal visual hull using 4D Delaunay meshing

[Aganj et al 2007]

Approach

• Extend the previous algorithm to compute 4D visual hulls \Rightarrow 4D representation of the scene

Advantages over frame-by-frame computations

- Exploits time redundancy
- Continuous representation, allowing spatio-temporal smoothing
- Reduction of flickering artefacts in synthesized views
- Handles naturally topological changes along time
- Requires an efficient implementation of DT in \mathbb{R}^4

(日本) (日本) (日本)

æ

Problem

To model moving surfaces undergoing large deformations and topology changes

Our approach

- Represent the interface by a triangular mesh embedded in the restricted 3D DT of interface points
- Update the mesh at each time step by updating the RDT

The algorithm at time step *n*

input: $\mathcal{P}_n = sample$, Ω_n , $D_n = \text{Del}_{|\Omega_n}(\mathcal{P}_n)$

- 1. Move the points of \mathcal{P}_n
- 2. Adapt the sample resolution $\rightarrow \mathcal{P}_{n+1}$
 - 2.1 replace a too short edge of D_n by its midpoint
 - 2.2 add the midpoint of a too long edge
- 3. Deal with topology changes
 - 3.1 discard tetrahedra that have been inverted

$$\Omega_{n+1} = igcup \{ ilde{ au} | au \in {\mathcal D}_n, ext{orient}(ilde{ au}) imes ext{orient}(au) < {\mathbf 0} \}$$

3.2
$$D_{n+1} = \text{Del}_{|\Omega_{n+1}|}(\mathcal{P}_{n+1})$$

3.3 remove the vertices whose incident simplices all share the same label

Meshing 3D domains by Delaunay refinement

The surface mesher

- inserts points on the surface S
- triangulates the ambient space and extracts the Delaunay triangulation restricted to S
- ► controls the shape of the triangles of Del_{|S}(P)

• Image: A image:

Meshing 3D domains by Delaunay refinement

The surface mesher

- inserts points on the surface S
- triangulates the ambient space and extracts the Delaunay triangulation restricted to S
- controls the shape of the triangles of $\text{Del}_{|S}(\mathcal{P})$

Hence

- it can triangulate the domain O bounded by S at no additional cost
- but does not provide control on the shape of the tetrahedra inside O

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ト

크
Meshing volumes with curved boundaries [Oudot et al. 05]

3-d mesh refinement algorithm

- 1. Run the surface meshing algorithm
- Insert points inside O to remove the bad elements of Del_{|S}(P) and Del_O(P)

Sizing field

 $\psi(x)$ defined over O

Basic procedures

Sizing field

 $\psi(x)$ defined over O

Basic procedures

Bad elements

bad facet $f : r_f > \alpha \psi(c_f)$ or f has a vertex $\notin S$ bad tet. t: tetrahedron whose circumscribing ball has radius $r_t > \psi(c_t)$ or a radius-edge ratio $> \rho$

・ 白 ・ ・ ヨ ・ ・ 日 ・

Step 2 : Apply the following rules in order

- 1. if $f \in \text{Del}_{|S}(\mathcal{P})$ is a bad facet, $\text{refine}_{f}(f)$
- 2. if $t \in \text{Del}_{\mathcal{O}}(\mathcal{P})$ is a bad tetrahedron,
 - 2.1 if ct is included in a surface Delaunay ball Bt, refine_face(f)
 - 2.2 else refine_tet(t)

< 同 > < 回 > < 回 > <

Step 2 : Apply the following rules in order

1. if
$$f \in \text{Del}_{|S}(\mathcal{P})$$
 is a bad facet, $\text{refine}_{f}(f)$

- 2. if $t \in \text{Del}_{\mathcal{O}}(\mathcal{P})$ is a bad tetrahedron,
 - 2.1 if c_t is included in a surface Delaunay ball B_f ,

```
refine_face(f)
```

2.2 else refine_tet(t)

Properties

- 1. For appropriate α and ρ , the algorithm terminates
- 2. $\mathrm{Del}_{|S}(\mathcal{P}) = \mathrm{Del}_{|S}(\mathcal{P} \cap S)$ (cf. def of bad facet)
- 3. hence $\text{Del}_{S}(\mathcal{P})$ is a 2-triangulation isotopic to S $\text{Del}_{O}(\mathcal{P})$ is a 3-triangulation isotopic to O

Multibody mesh generation from segmented images

- input : a segmented 3D image (each voxel has a label)
- label of a tetrahedron: label of its circumcenter
- boundary facet : dual to a Voronoi edge whose endpoints have two different labels

Multibody mesh generation from segmented images input : a segmented 3D image (each voxel has a label) label of a tetrahedron: label of its circumcenter boundary facet : dual to a Voronoi edge whose endpoints have two different labels

- We mesh simultaneously the various tissues using Delaunay refinement
- The boundary facets produce a good approximation of the interfaces

all boundary surfaces are water tight and don't intersect each other

The tetrahedra of a given label produce a good approximation of the associated tissue

Meshing 3D domains with piecewise smooth boundaries [Dey & Levine]

Protecting balls

- centered on the sharp features F of S
- ▶ *B* cannot contain the center of $B' \neq B$
- the balls cover F
- no 3 balls intersect

Meshing 3D domains with piecewise smooth boundaries [Dey & Levine]

Protecting balls

- centered on the sharp features F of S
- *B* cannot contain the center of $B' \neq B$
- the balls cover F
- no 3 balls intersect

Algorithm

- Use the weighted DT
- Insert the protecting balls first
- Insert unweighted points inside O as usual

Meshing 3D domains with piecewise smooth boundaries

- 6052 vertices
- 37106 cells
- 8,87° smallest dihedral angle
