Operating Systems: Distributed Applications

Fabrice Le Fessant and Albert Cohen

INF 552 Operating Systems Ecole Polytechnique, Palaiseau

13 mars 2007

Introduction

- 2 Internet Protocols
- 3 Network File-System : NFS
- Peer-to-Peer File-Sharing

- Lecture on Distributed Systems
 - Just for fun !
- Computer Class Room on Sockets/Threads
 - To continue the forum project

Open Systems Interconnection Basic Reference Model

- Layer 7 : Application layer (FTP, NFS)
- Layer 6 : Presentation layer (XDR)
- Layer 5 : Session layer (TCP)
- Layer 4 : Transport layer (TCP, UDP)
- Layer 3 : Network layer (IP)
- Layer 2 : Data Link layer (Ethernet, ADSL)
- Layer 1 : Physical layer (Cable, Fiber)

In this lecture, we consider only the Application Layer

Consensus in Distributed Systems

- One huge army in the valley
- Two armies on the mountains on both sides
- They can win IF AND ONLY IF they attack together at the same moment
- Their messengers must cross the valley, maybe got killed or delayed
- Can they win?
- Consensus is not achievable in distributed systems with failures.
- Most protocols are either centralised, or have to refer to a central authority in case of problem.

Finding Information on Distributed Protocols

RFC : Request for Comments

- RFC-Editor:http://www.rfc-editor.org/rfc.html
- IETF : Internet Engineering Task Force
- IANA : Internet Assigned Numbers Authority

On your Unix/Linux computer

• /etc/services : ports for services

Network Protocol : TCP/IP

- Computers have numeric addresses (IPv4/IPv6) : "129.104.247.1"
- Computers have symbolic names : "kelen.polytechnique.fr" (host name and domain name)
- Some protocols are responsible for routing (BGP) and name translation (DNS)

Application Protocols

- Client-Server Protocols : SMTP, FTP, HTTP
- Distributed File-Systems : NFS, SMBFS, AFS
- Peer-to-Peer Protocols : Kad, Bittorrent, Skype

1 Introduction

3 Network File-System : NFS

Translation of symbolic names to IP addresses

- UDP or TCP on port 53
- Finding the IP address of kelen.polytechnique.fr:
 - Query A IN kelen.polytechnique.fr to your name server
 - Reply A IN kelen.polytechnique.fr DA 129.104.247.1
 - Reply has an authority: NS IN polytechnique.fr DNAME dns1.polytechnique.fr
 - Reply may contain more info: A IN dns1.polytechnique.fr DA 129.104.1.1
- Known names are stored in /etc/hosts
- Local name servers are stored in /etc/resolv.conf.

< 口 > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Typical Mail Path

- Mailer <u>SMTP</u> SMTP Relay The mail is delivered to your Internet Provider SMTP Relay.
 SMTP Relay <u>SMTP</u> SMTP Host The mail is delivered to each recipient SMTP Host
 SMTP Host <u>POP/IMAP</u> Mail Reader
 - Each recipient downloads the mail locally from the SMTP Host

RFC 821, Aug. 1982

- Many RFCs : 821 (SMTP), 822 (Mail), 1870, 2920, ... (extensions), 2821 (new proposal)
- Port : 25, Protocol : TCP

A mail contains

- A sender address
- Some recipients (fully qualified addresses)
 - Not presented in the mail (Bcc)
 - Translated automatically (mailing-lists)
- A content in 7bit format. Other formats are encoded :
 - base64 [a-zA-Z0-9+/]
 - quoted-printable [=00]

Salut,

Comment tu vas ?

-- Fab

An example : fabrice.le_fessant@inria.fr

- DNS Query: MX IN inria.fr
- DNS Reply: list of servers with weight: concorde.inria.fr, 10; backup.inria.fr, 5
- Try to propagate the mail in turn to each server in the list, by decreasing weight.

SMTP Protocol

A Text-Based Protocol

- Human readable
- CR-LF ($\r\n$) as line terminator

SMTP Commands

- HELO or EHLO : for connection
- MAIL FROM : identifying the sender
- RCPT TO : identifying the recipients
- DATA : the content of the mail (finished by a single . line)
- VRFY : testing an email address
- RSET : resetting an email
- QUIT : for ending the connection

An example of communication with my SMTP relay

```
peeromane:~/C8% telnet smtp.free.fr 25
220 smtp4-g19.free.fr ESMTP Postfix
EHLO mycomputer.free.fr
250-Hello mycomputer.free.fr from smtp4-q19.free.fr
250-PIPELINING
250-STZE 10000000
250-VRFY
250-ETRN
250 8BITMIME
MAIL FROM: fabrice@lefessant.net
250 Ok
RCPT TO: fab@lefessant.net
250 Ok
DATA
354 End data with <CR><LF>.<CR><LF>
Coucou, Comment ca va ?
 - Fabrice
```

250 Ok: queued as 72B8567482

RFC 959 > 765, Oct. 1985

- A protocol to download files from and upload to a server
- The server waits on port 21
- The protocol distinguishes between connections :
 - Control connections for commands and reply statuses
 - Data connections for file content
- A complex protocol for firewalls
 - The firewall must understand the commands, since it may have to forward data connections !

Example session

```
220 Service ready
> USER JohnDoe
331 User name ok, need password
> PASS mumble
230 User logged in
> PORT 192,168,150,80,14,178
200 PORT command successful.
> LIST
150 Opening ASCII mode data connection for file list.
226 Transfer complete.
> CWD /tmp
250 CWD command successful.
> TYPE A
200 Command OK
> RETR test.txt
150 File status ok; about to open data port 3762
226 Closing data connection, transfer successful
> OUIT
221 Goodbye.
```

HTTP : Hyper-Text Transfer Protocol

RFC 2616 (HTTP/1.1), Jun. 1999

- A protocol to download files from a Web-server, on a single connection.
- The server waits on port 80
- Communcations are made of requests, each request containing :
 - A query/reply line
 - A set of headers
 - An empty line for separation
 - A data block
- The data block length is specified either by one of the headers, or by the end of the connection (before HTTP 1.0).
- Different requests : GET, POST, HEAD, ...

Need for Secured Internet Connections :

- E-Commerce : sending your Credit Card Number
- Privacy : protecting personal data transmitted

Secured Connections offer :

- Authentication : need to identify the other side and trust it
- Encryption : data should not be compromised to a third-party listening to the connection packets (man-in-the-middle attack)

SSL/TLS is easily used everywhere (layer 5)

- HTTPS = HTTP + SSL
- Used also for POP3, IMAP, SMTP, etc...

How to use Cryptography to secure connections?

- Each host has a pair of cryptographic keys
 - One key is secrete (nobody else must know it)
 - One key is public (everybody should know it)
- A certificate signed by a trusted party (Verisign...) guarantees the public key owner.
- Asymmetric encryption (slow) is used to exchange a temporary session key
- Symmetric encryption (fast) with the session key is used to exchange data

Distributed File-System Requirements

Transparency

- Access Transparency
- Location Transparency
- Mobility Transparency
- Performance Transparency
- Scaling Transparency
- Concurrency control
- Replication
- Fault-Tolerance
- Heterogeneity
- Security
- Consistency

Mounting NFS Partitions

- /etc/exports specifies which sub-trees are shared (server)
- /etc/fstab specifies which partitions are mounted (client)
- Partitions can be mounted, depending on server failures :
 - hard, clients are suspended while waiting
 - soft, clients are released after a few retries

< ロ > < 同 > < 回 > < 回 >

- Either inside the Kernel, or a daemon process
- Stateless server :
 - Access control on each request
 - No/bad file locking
- Server caching :
 - Read-ahead, reads blocks following recently read blocks
 - Write-Through or Write-Back caching
- What are the problems of each approach?

4 A N

Semantics different from UNIX FS Semantics

• File handles used by Clients :

- File-System ID on Server
- i-Node number of File
- i-Node generation of Server

SUN RPC translated to XDR, UDP and TCP

1 Introduction

- 2 Internet Protocols
- 3 Network File-System : NFS
- Peer-to-Peer File-Sharing

Definition of a Peer-to-Peer Network

- All computers are *peers*, i.e. both client and server
- Thousands to millions of computers are inter-connected, all over the world
- Computers join and leave the network all the time

File-Sharing Requirements

- File Discovery : find the file you are interested in
- *File Localization :* find some peers sharing the file you are interested in
- Efficient File Download : download the file as fast as you can
- *Sharing Incentives :* force other peers to share as much as they can

Definition of a Peer-to-Peer Network

- All computers are *peers*, i.e. both client and server
- Thousands to millions of computers are inter-connected, all over the world
- Computers join and leave the network all the time

File-Sharing Requirements

- File Discovery : find the file you are interested in
- *File Localization :* find some peers sharing the file you are interested in
- Efficient File Download : download the file as fast as you can
- Sharing Incentives : force other peers to share as much as they can

Examples

- File-Sharing : Kad, Bittorrent, Edonkey (Emule), Fasttrack (Kazaa), ...
- Telephony : Skype, ...

In this lecture :

- How to localize files ?
 - Unstructured networks
 - Structured networks
- How to download files ?

< ロ > < 同 > < 回 > < 回 >

- File-Sharing : Kad, Bittorrent, Edonkey (Emule), Fasttrack (Kazaa), ...
- Telephony : Skype, ...

In this lecture :

- How to localize files ?
 - Unstructured networks
 - Structured networks
- How to download files?

How to localize a ressource in Unstructured Networks

Diffuse the request to the whole network (Gnutella)?

Operating Systems: Distributed Applications

Bloom Filters

A Bloom Filter is an array of bits which summarizes which files are stored on a peer

- Compute different hash functions for each file : file \rightarrow int \times int \times int \times ...
- Set one bit per hash function in the filter
- A file can be present only if all the bits are set

How to use Bloom Filters to reduce diffusion?

- Each peer sends its Filter to all its neighbours.
- Filters can be combined (ORed) to summarize which files are stored on a set of peers.
- Filters are easy to compute, most efficient when mostly null, and easy to compress when mostly null !
- Forward a query only if the Filter tells you to do so

Bloom Filters

A Bloom Filter is an array of bits which summarizes which files are stored on a peer

- Compute different hash functions for each file : $file \rightarrow int \times int \times int \times ...$
- Set one bit per hash function in the filter
- A file can be present *only if* all the bits are set

How to use Bloom Filters to reduce diffusion?

- Each peer sends its Filter to all its neighbours.
- Filters can be combined (ORed) to summarize which files are stored on a set of peers.
- Filters are easy to compute, most efficient when mostly null, and easy to compress when mostly null !
- Forward a query only if the Filter tells you to do so

Structured Networks

- Distributed Hash Tables (Chord, Kademlia, Broose,...)
- Skip Lists
- Voronets

Often O(logN) complexity

- For exact queries
- For range queries
- For multiple-criteria queries

< ロ > < 同 > < 回 > < 回 >

Finding the value associated with an entry

- Compute a key from the entry using a hash function (usually, an integer modulo the size of the array)
- Find the node in the hash table associated with that key (usually, a list stored at the key index in an array)
- Find the entry in the list, and the corresponding associated value
- If $| array | \ge | values |$, lookup in O(1)

Application to distributed systems?

Cryptographic Hash Functions

- MD4, MD5, SHA1, ...
- Transform any string in a short string (16-20 chars)
- Collisions are possible (of course !) but unlikely
- Secure :
 - Hard to reverse a hash
 - Hard to generate a collision

Replace indexes by hashes

- Each peer has a hash (randomly generated)
- Each peer stores a list for a hash
- In fact, each peer stores a list for all hashes closed to its hash

Cryptographic Hash Functions

- MD4, MD5, SHA1, ...
- Transform any string in a short string (16-20 chars)
- Collisions are possible (of course !) but unlikely
- Secure :
 - Hard to reverse a hash
 - Hard to generate a collision

Replace indexes by hashes

- Each peer has a hash (randomly generated)
- Each peer stores a list for a hash
- In fact, each peer stores a list for all hashes *closed* to its hash

• All clients are put on a logical ring, depending on their random identifier

イロト イヨト イヨト イヨト

- Each client has a routing table, containing peers (*fingers*) with particular identifiers :
 - Peer *id* has one neighbour in the interval $[id..id + \frac{1}{2}]$, $[id + \frac{1}{2}..id + \frac{1}{4}]$, $[id + \frac{1}{4}..id + \frac{1}{8}]$, $[id + \frac{1}{8}..id + \frac{1}{16}]$,...

• To find a file with hash *hash*, just forward the query to the peer p_i (finger *i*) such that $hash \in [id + \frac{1}{2^{(i-1)}}..id + \frac{1}{2^i}]$

- The message is then forwarded again, with the guarantee that each time, the interval will decrease
- When no interval is found, the peer is responsible for replying

< ロ > < 同 > < 回 > < 回 >

Kademlia : trees as routing tables

2

42/43

How to make peer-to-peer download more efficient than client-server download ?

- A file is located on many peers
- Verify that it is the same file
 - Use a cryptographic hash functions (MD5, SHA1)
- Download the file from as many peers as possible :
 - Split the file in blocks
 - Verify each block after download
 - Share each block as soon as possible

Bittorrent Incentives

- Share a file with only 4 other peers
 - 3 peers are the best uploaders
 - 1 peer is chosen randomly
- Change every 30 seconds

How to make peer-to-peer download more efficient than client-server download ?

- A file is located on many peers
- Verify that it is the same file
 - Use a cryptographic hash functions (MD5, SHA1)
- Download the file from as many peers as possible :
 - Split the file in blocks
 - Verify each block after download
 - Share each block as soon as possible

Bittorrent Incentives

- Share a file with only 4 other peers
 - 3 peers are the best uploaders
 - 1 peer is chosen randomly
- Change every 30 seconds
