# Proactive Services

*Nguyen Hoa Binh*  
LSR-IMAG  
Grenoble

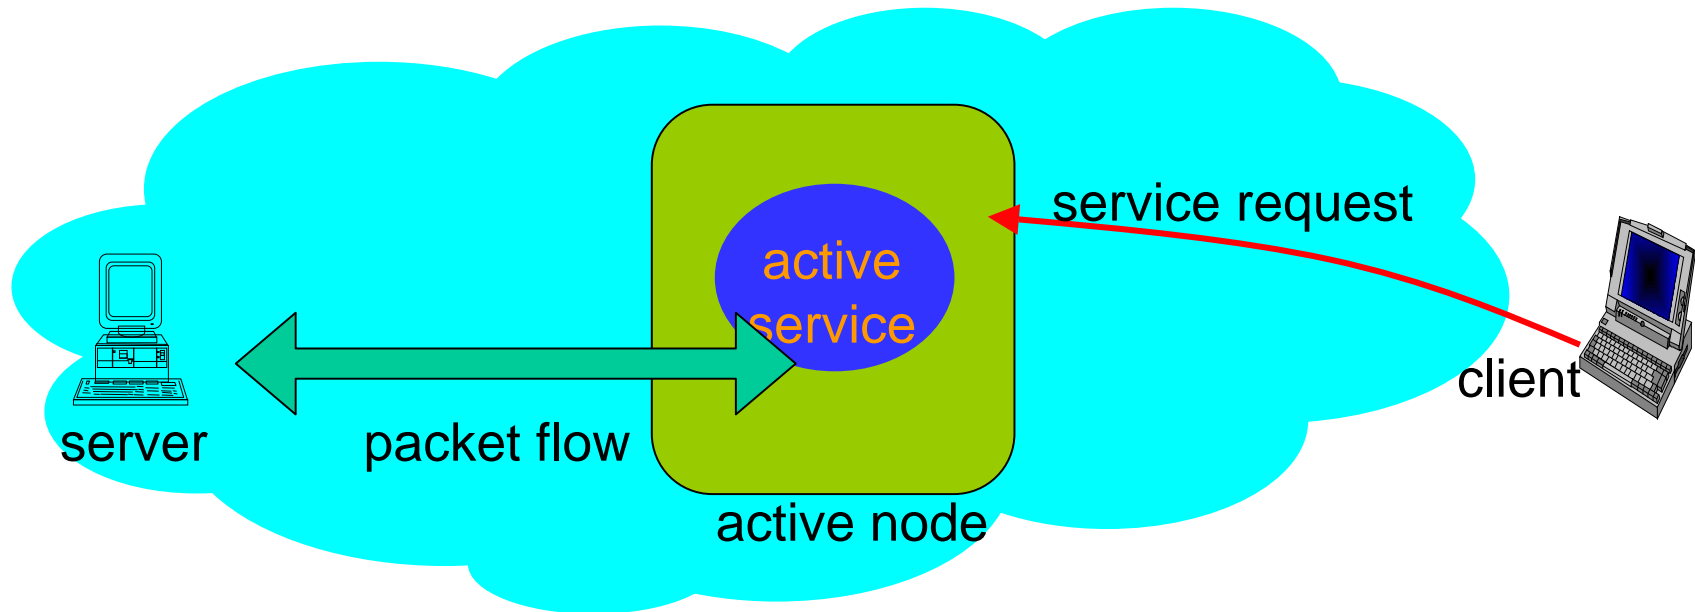

# Outline

---

- Proactive Services
- Active Node Architecture
- Applications
- Implementation
- Future Works

# Why Proactive Services ?

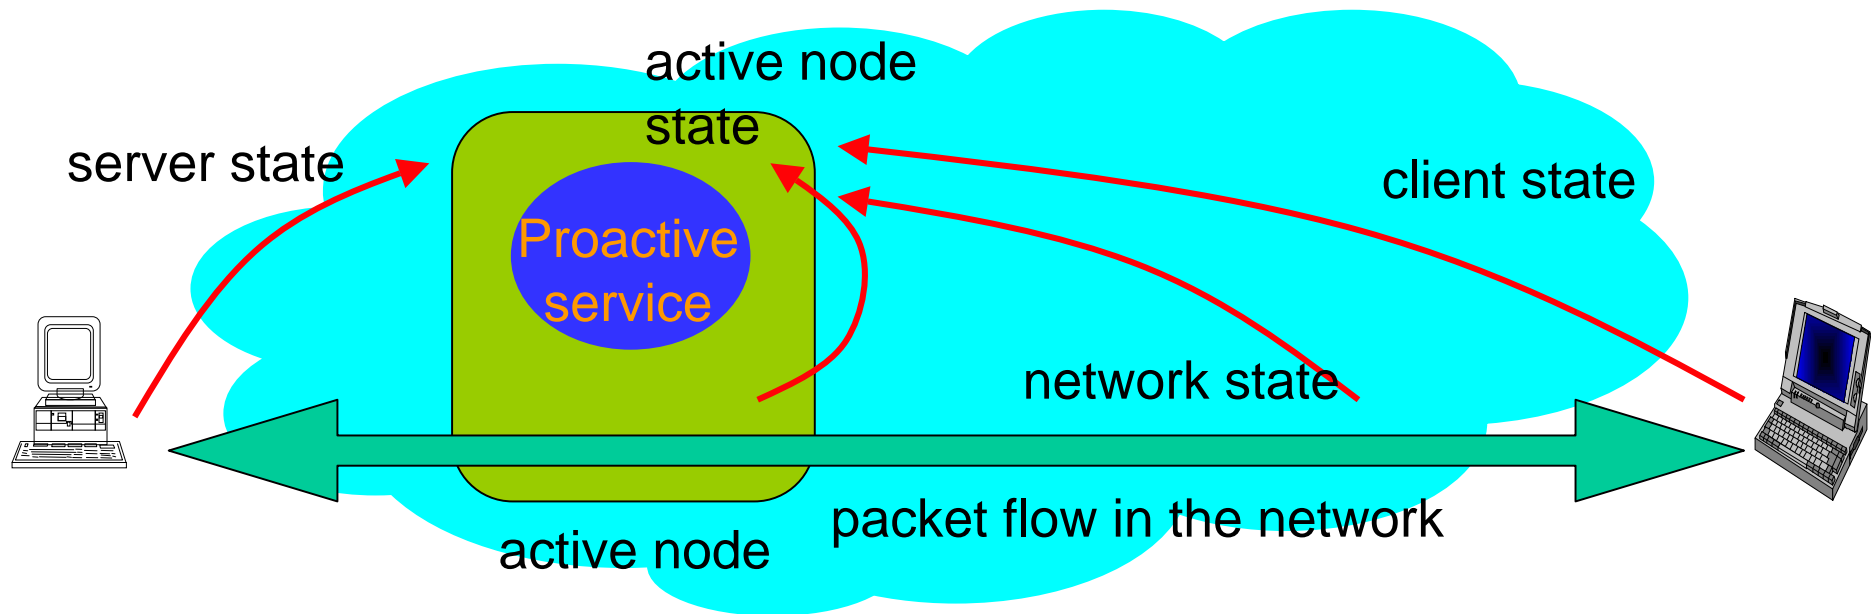

---

- End-point Applications need active services from networks
- Active services need information about states from end-point application
- Active services need information about states from networks
- User role needs to be reduced to supervision

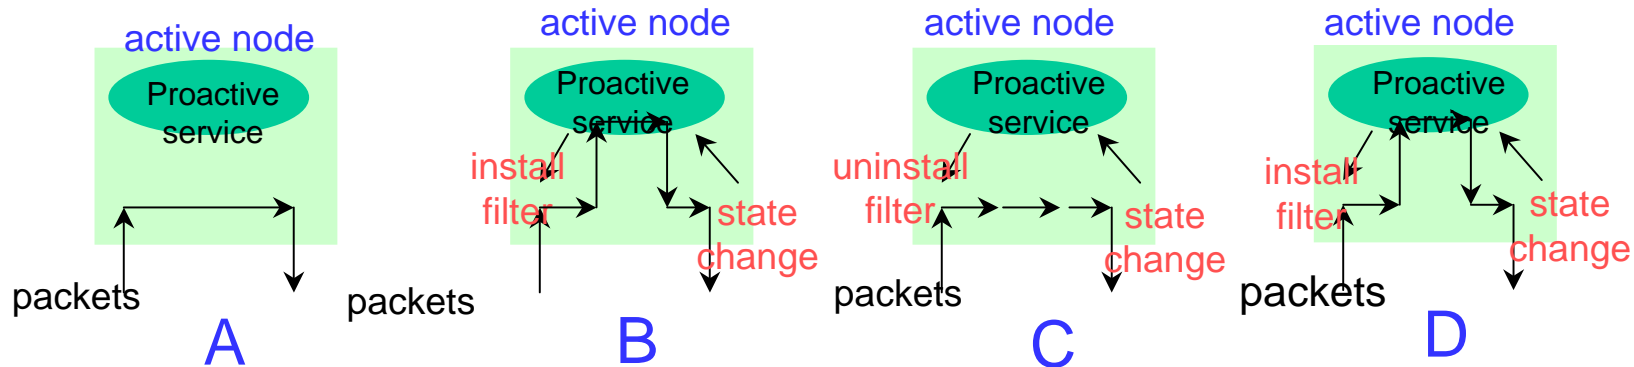

# What is a proactive service?

---

- Active service able to react to the changes in the environment without the intervention of the user
- Get users out from interaction loop – react faster than human speed

# Proactive Service Behavior

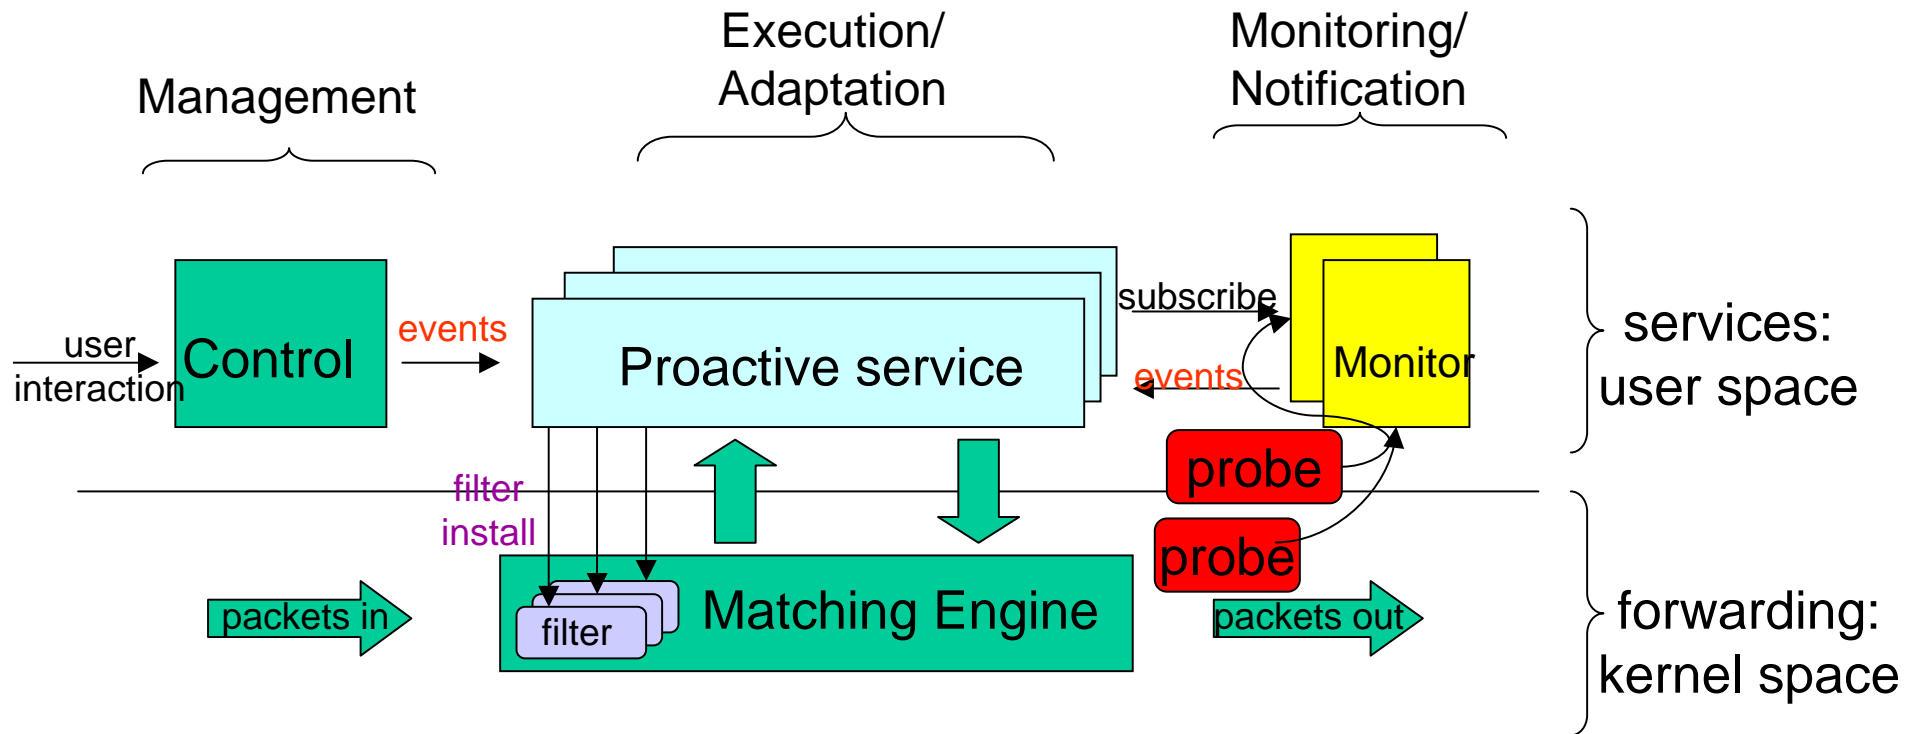

A – when a service is activated, the state of the environment is such that no processing is required. **The service sleeps and packets are not passed to the service**

B – an event signaling a congestion link is sent to the service. **It wakes up and installs an appropriate packet filter.** Packets are passed to the service

C- when the state changes again (congestion disappears), another event is sent to the service that **uninstalls the filter so that packets are no longer intercepted.** The service returns to sleep.

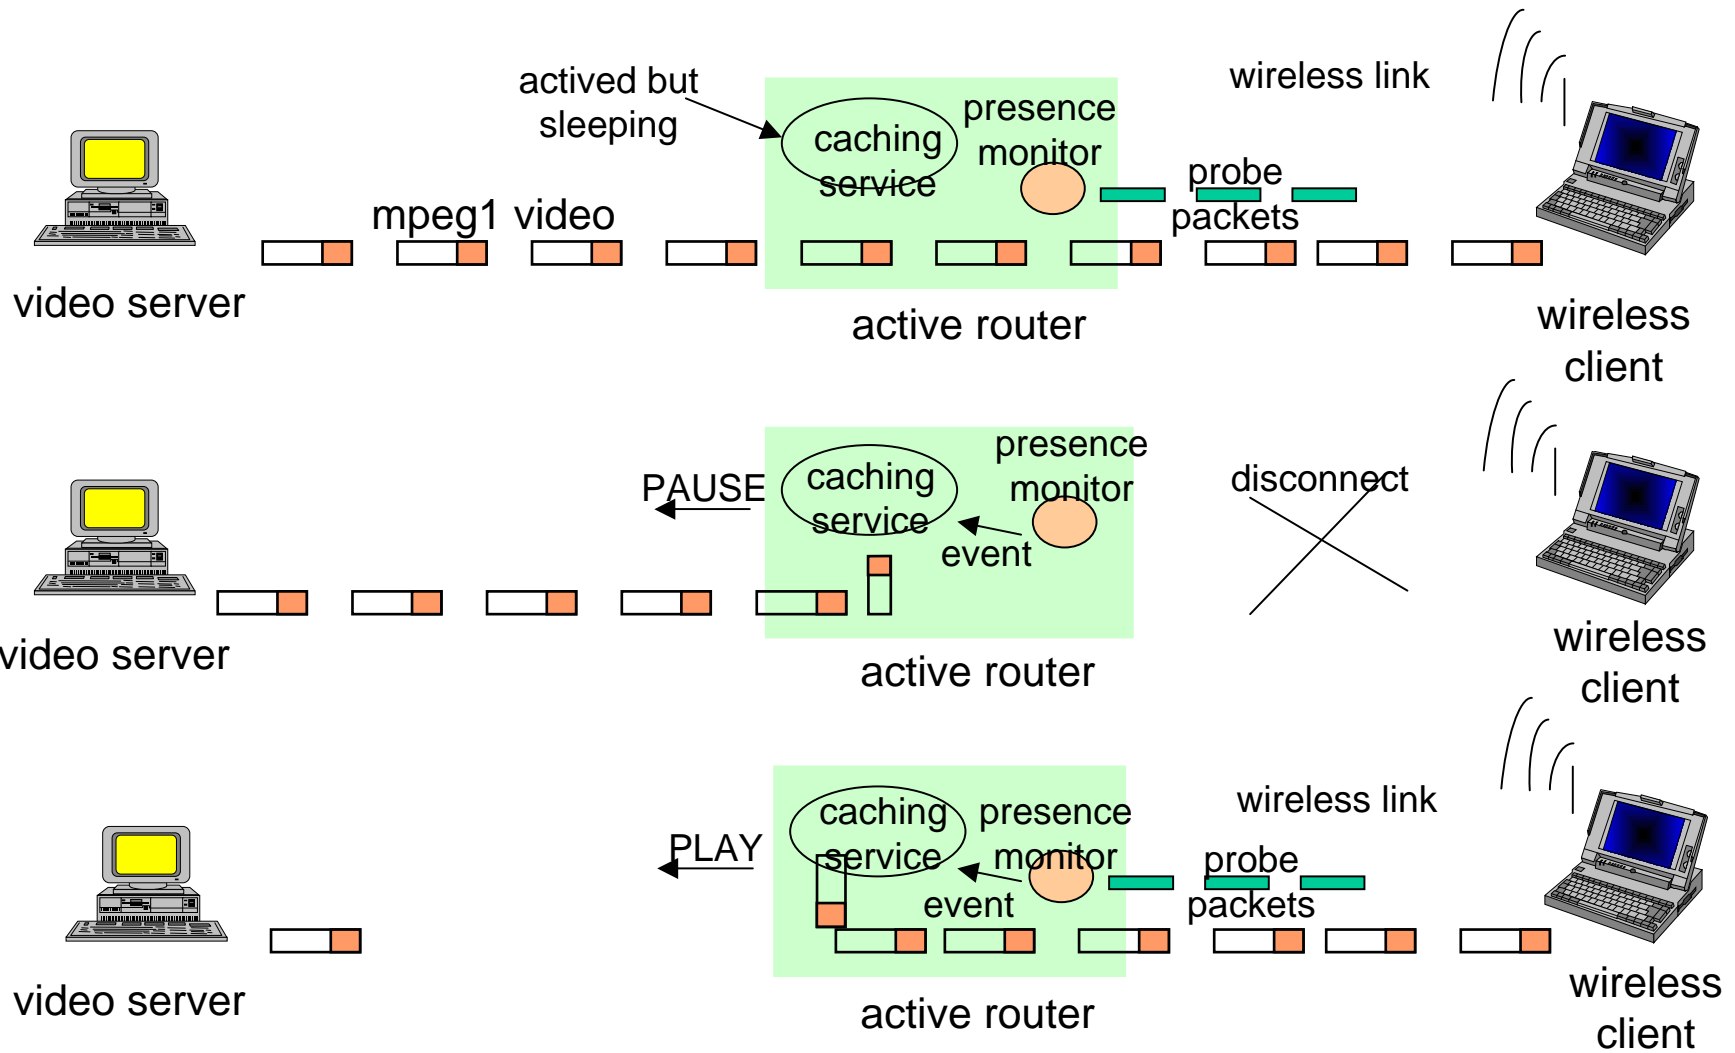

D - the whole process may repeat

# Active Node Architecture

- Association of proactive services with chosen packet flows is done dynamically by the services themselves
- Monitors are able to detect varying conditions in the environment (network, active nodes, services, users)
- An asynchronous notification mechanism allows monitors to notify proactive services about events

# Example of Caching Service

# Session Migration Service

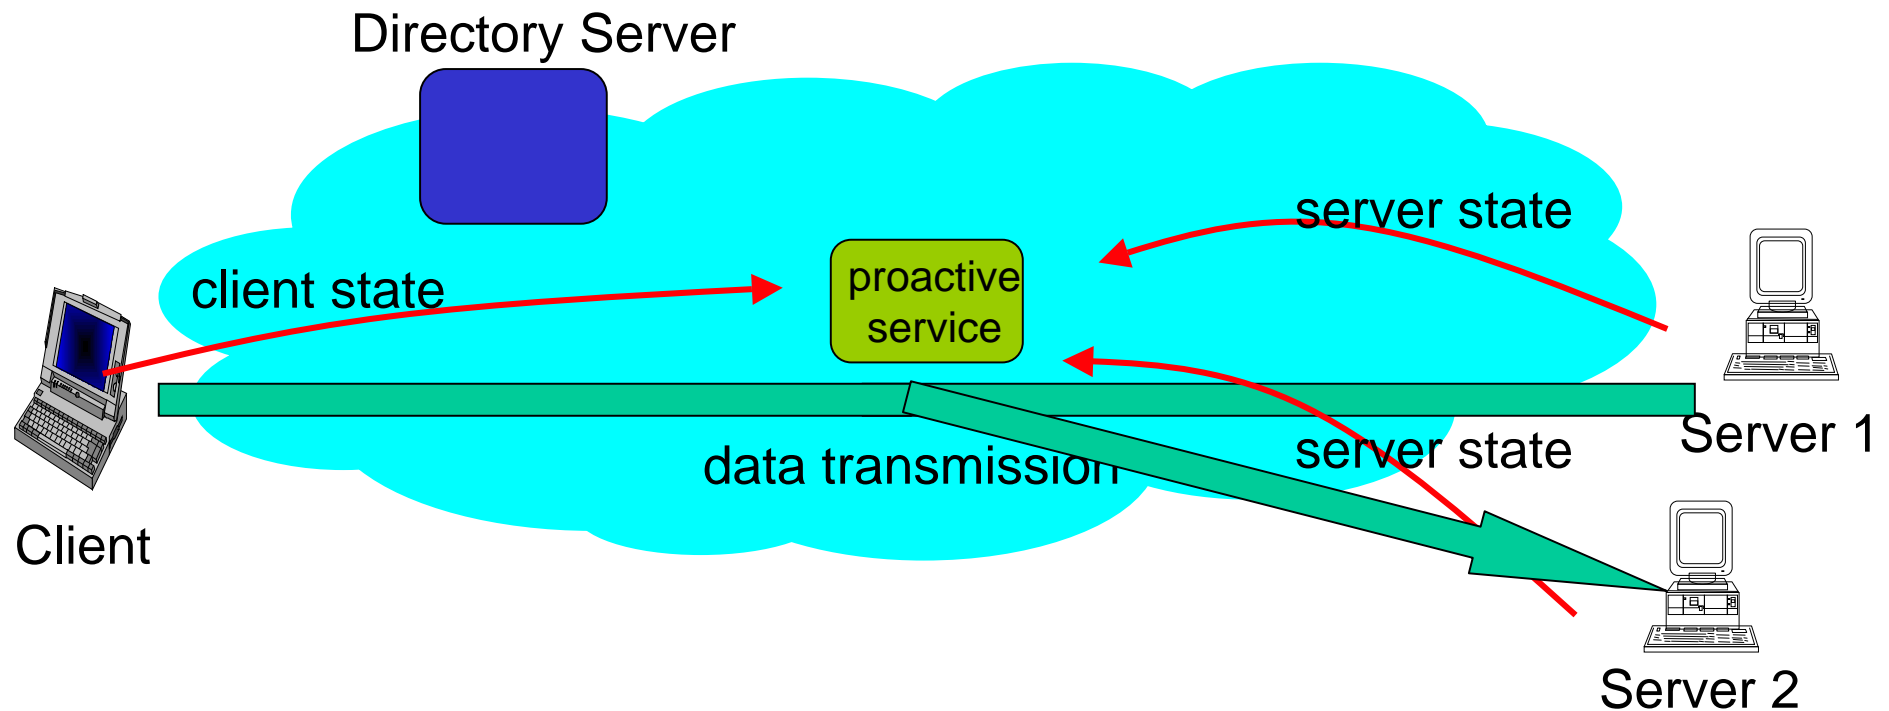

---

- What happens when the connection between the client and the server is degraded ? Server overloaded ? Server disconnected ? etc...

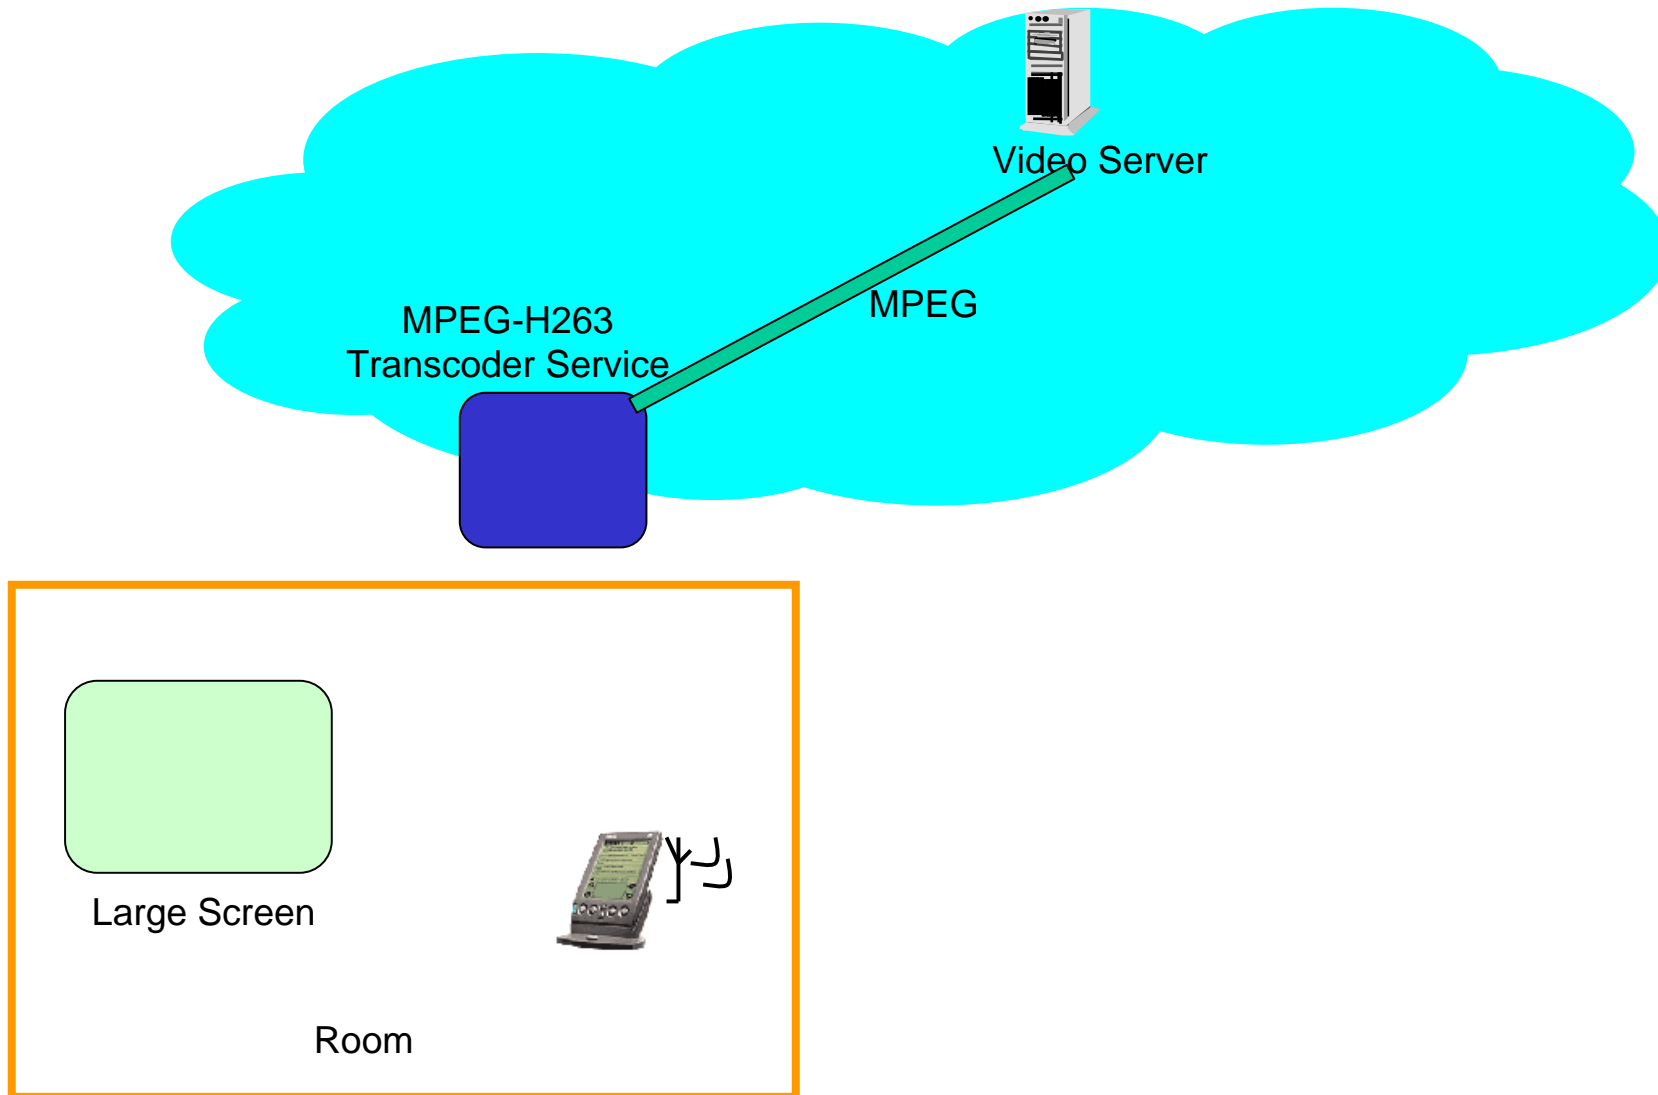

# Session Migration Service

- Proactive service establishes new data session with other servers

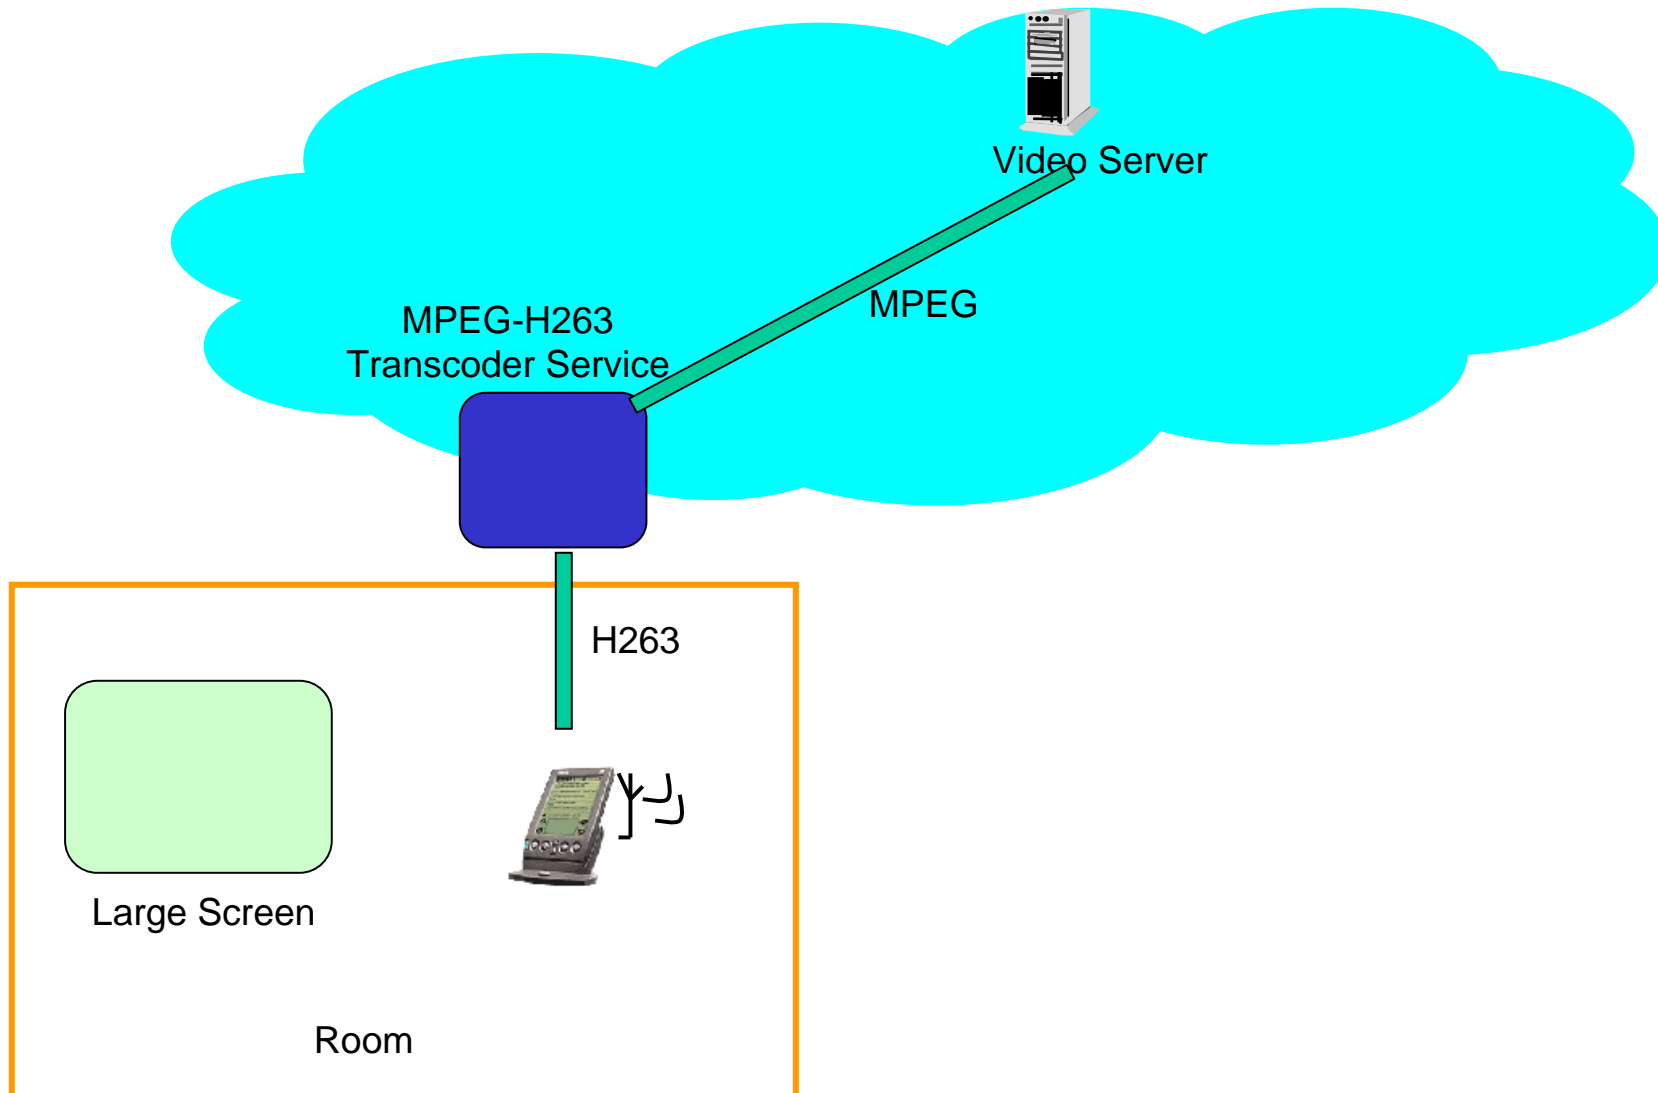

# Services for Ubiquitous Computing

---

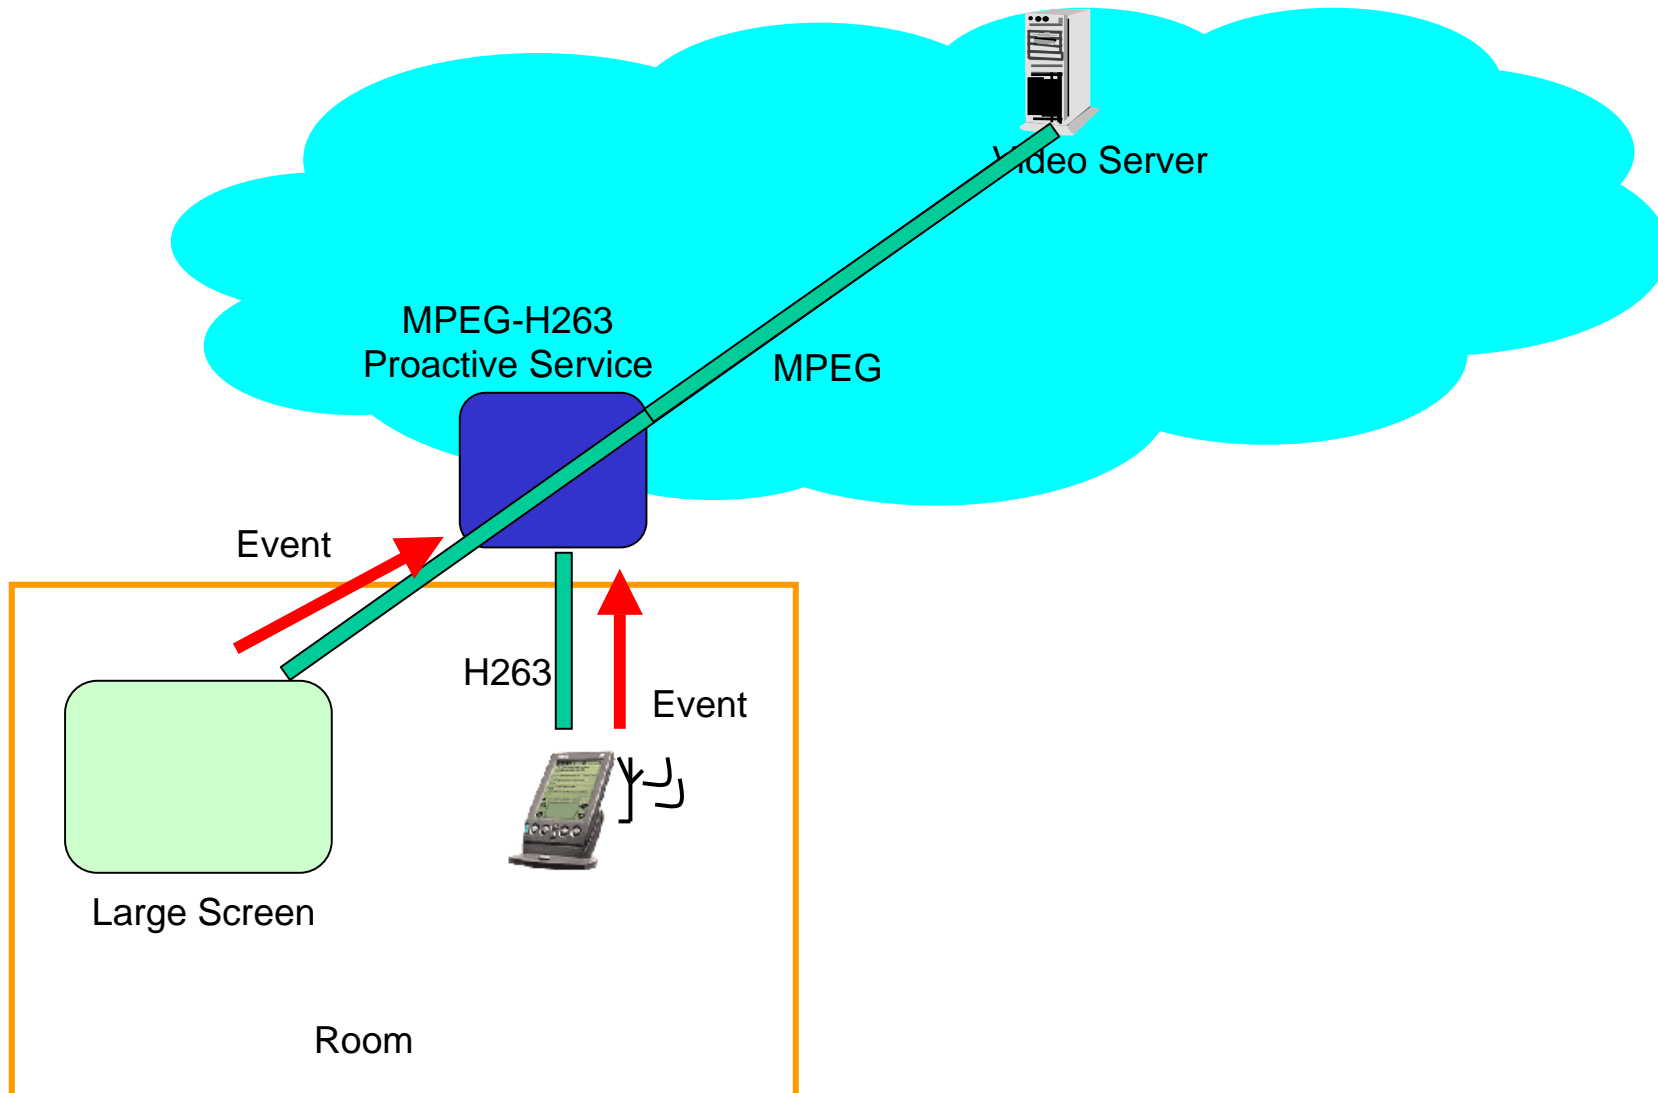

# Services for Ubiquitous Computing

---

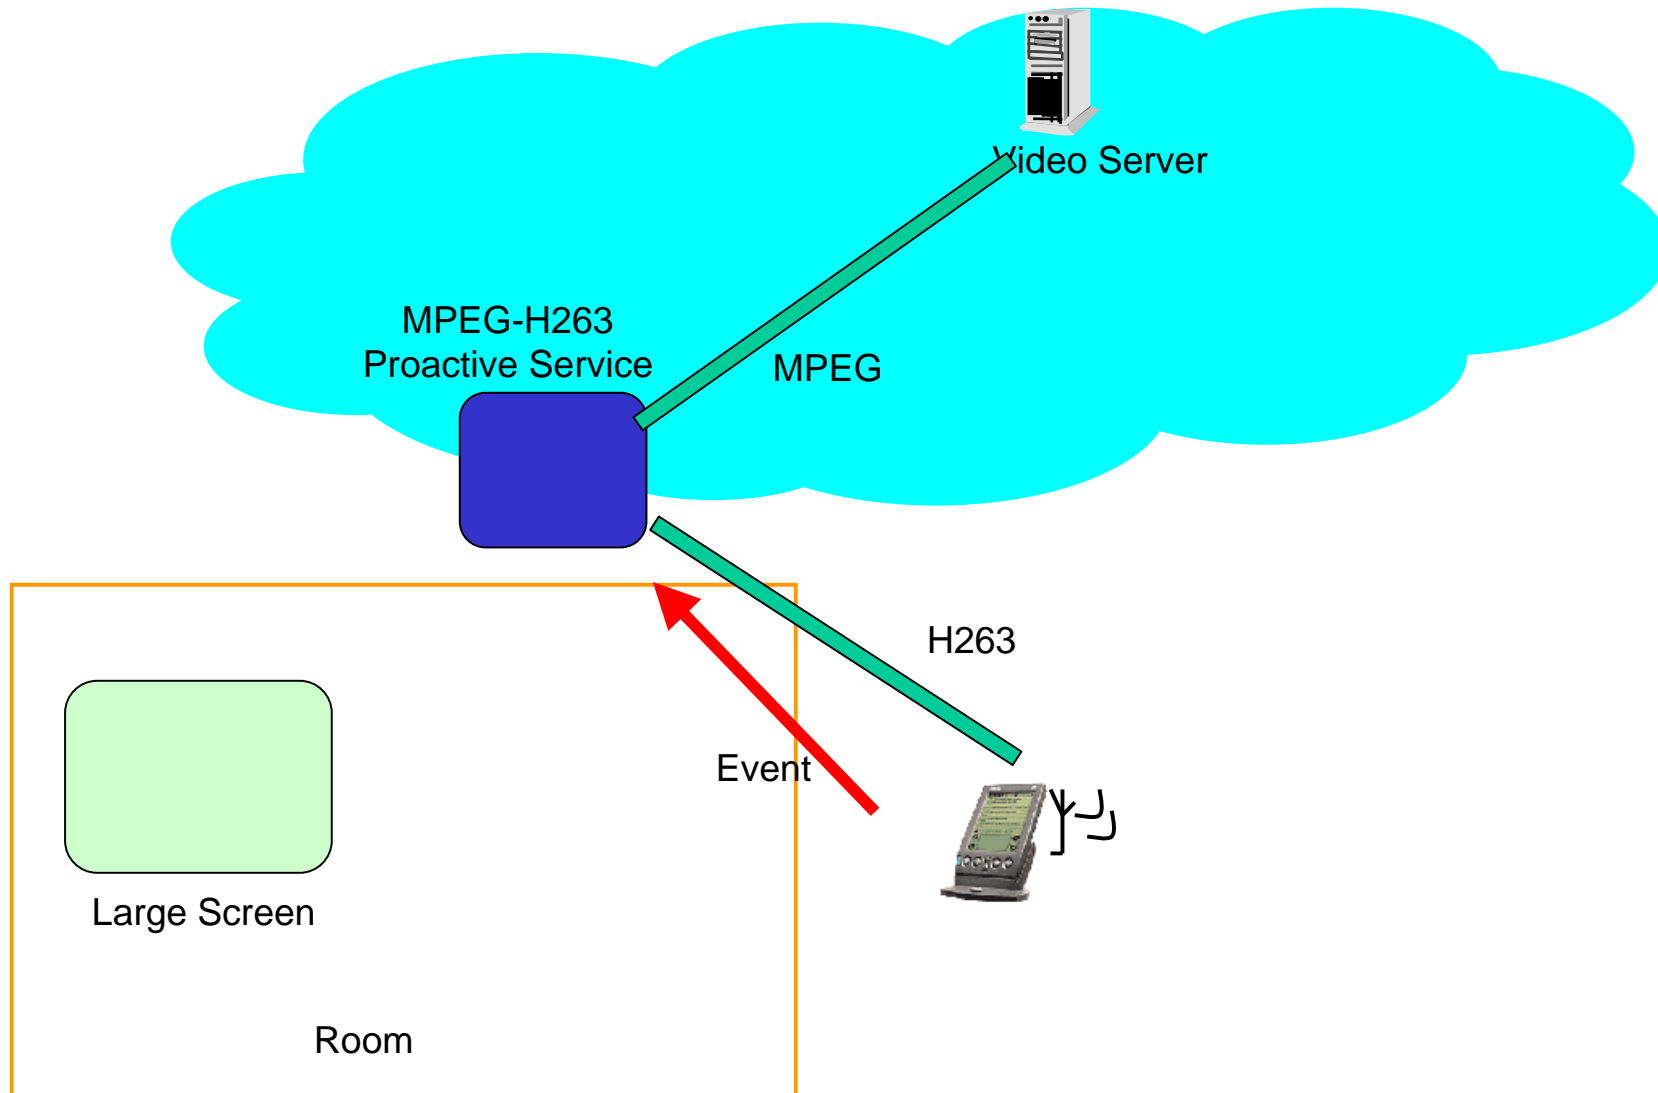

# Services for Ubiquitous Computing

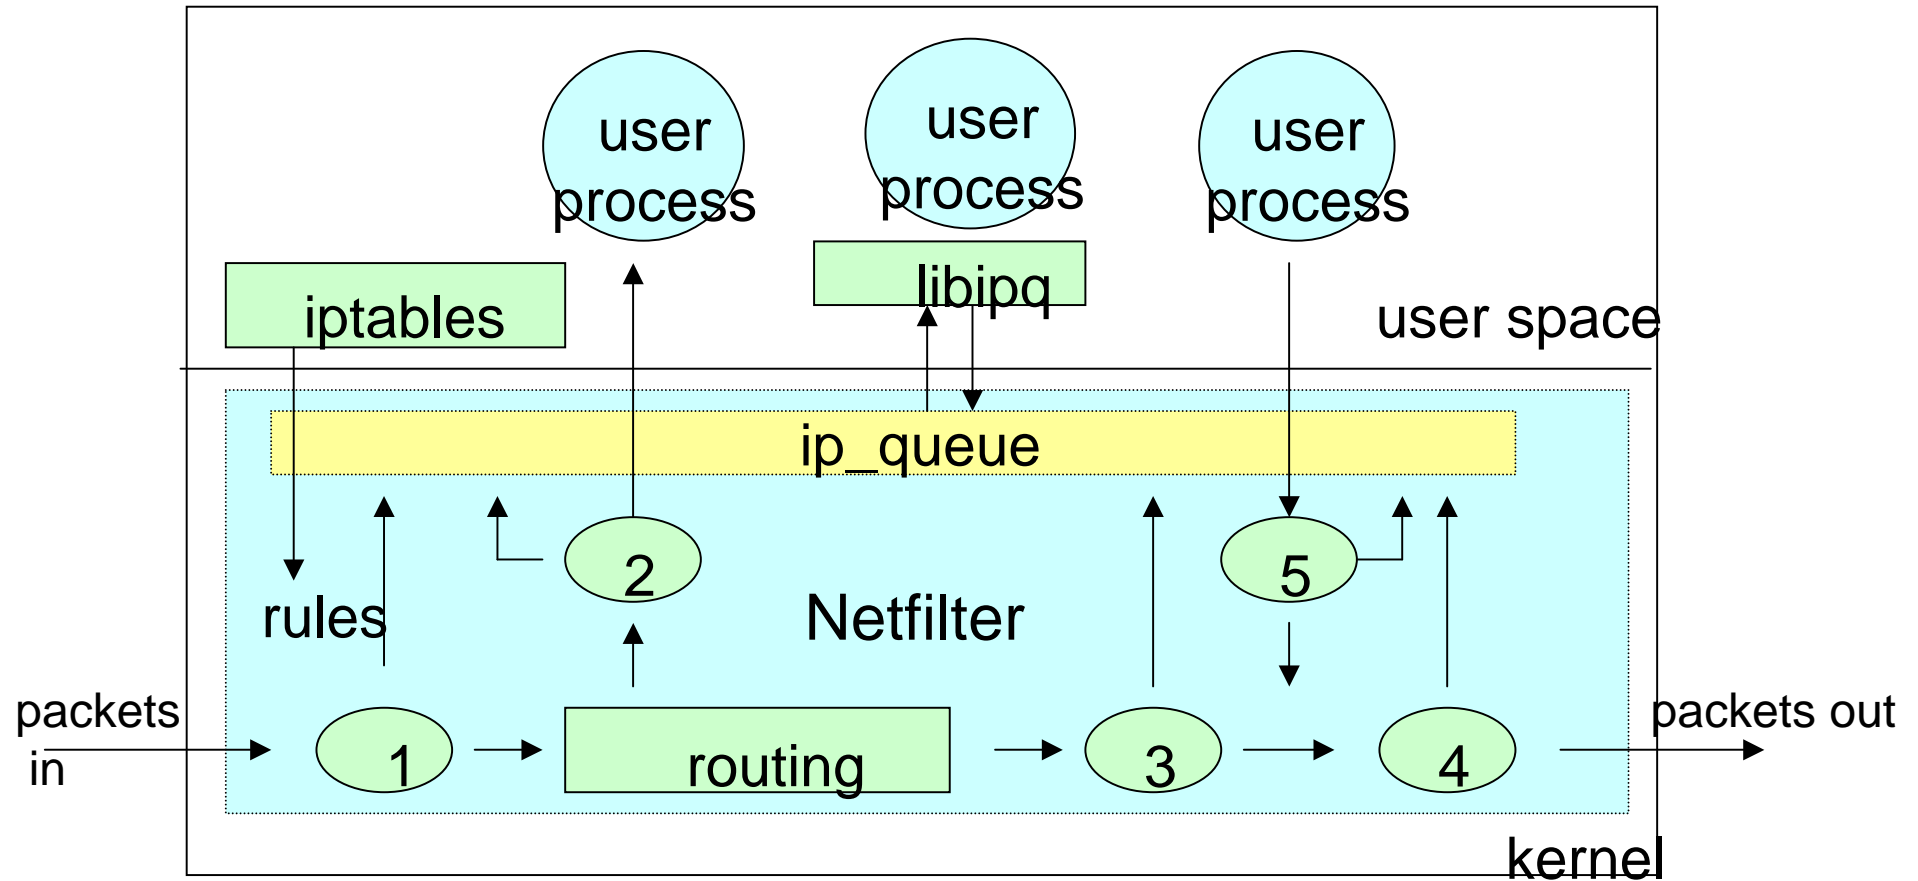

# Services for Ubiquitous Computing

---

# Implementation

Routeur running Linux kernel 2.4

# Implementation

---

- Netfilter and ip\_queue are modified to support forwarding of different packet flows to different user space processes
- Proactive services run as user space processes and can be written using C or Java language.
- An example of a user space active network node
- Node monitors the resources used by proactive services

# Future Works

---

- Provide a high level language for specifying proactive services
  - reason in terms of monitors, events, and actions
- Compiled into an implementation language such as C or Java
- Experiment with proactive services for different applications
  - ubiquitous computing
  - content distribution
  - sensor networks

# Dynamic Routing Service
